

F3 Completed-attempt failures and finite-window outcomes 4 agents; dependency 0; avoidance 0; fixed repair clock

● Read at dispatch --- First-order (dispatch) ■ Re-read at repair start --- First-order (start)

$p = 0.003435$ (4-line edits)

$p = 0.01556$ (16-line edits)

$p = 0.06872$ (64-line edits)

First-order $q = 1 - \exp(-\mu E)$: dispatch uses $E = \delta + R$; re-reading uses $E = R = 0.25$. At $\delta = 0$ both use $E = R$.

All ratios pool 30 seeds. Aggregate inputs do not identify ratio intervals. Completed attempts are selected by the queue and cutoff.

μ is nominal; the vertical line marks waiting time $1/\mu$. Windows are fixed per p ; no uncensored mean or dispatch distribution is inferred.
