

Waiting increases re-collision with a dispatch-time baseline

Horizontal solid line extends the observed $\delta=0$ simulation value as a reference, not additional scan points.
Dotted curves: nominal $q = 1 - \exp(-\mu E)$; $E = \delta + R$ at dispatch, $E \approx R$ when re-reading; $R = 0.25$.
Completed attempts are selected by the queue and cutoff. Pooled 30-seed ratios; no ratio intervals inferred.
